### Imaging In Percutaneous Musculoskeletal Interventions

This is one of the first books to deal specifically with imaging in percutaneous musculoskeletal interventions. The use of different imaging modalities during these procedures is well described. In the first chapter, the basic procedures and different guidance techniques are presented and discussed.

The musculoskeletal imaging section of OHSU Diagnostic Radiology provides comprehensive evaluation of bones, joints, muscles, and nerves. A

complete spectrum of imaging modalities is employed, including MRI, CT, ultrasound, x-ray and fluoroscopy, and all studies are performed on state of the art equipment. We use the latest imaging techniques in order to address the specific concerns of our referring clinicians.

Most musculoskeletal soft tissue biopsies are best performed using a high-frequency linear array probe (7 to 12 MHz). In exceptional cases, such as a deep lesion in an obese patient, a lower-frequency probe may be used but at the expense of spatial resolution. Cross-sectional imaging (whether CT or MRI) must be reviewed prior to the biopsy.

The role of image-guided consolidative procedures has expanded to meet the growing prevalence of osseous metastases. <sup>12</sup>Percutaneous injection of bone cement has proven applicability as a palliative measure for painful osseous metastases and as a preventative measure for impending pathological fractures.

Percutaneous musculoskeletal intervention is an attractive alternative to more invasive procedures and an indispensable tool for evaluating and managing hip pain. US is an ideal modality for imaging guidance owing to its low cost, portability, lack of ionizing radiation, and capability for real-time visualization of soft-tissue and bone structures during intervention.
